Infectious hazards of organophosphate exposures. Organophosphates are chemicals used in agriculture, industry, and medicine. They exert their primary toxicologic effects by irreversible inhibition of an enzyme called acetylcholinesterase. This enzyme regulates the cholinergic pathways that are responsible for controlling the actions of muscles, glands, and the autonomic nervous system. Poisoning with organophosphate insecticides may result in acute cholinergic symptoms. In humans and other animals, the signs include miosis, salivation, lacrimation, bronchospasm, vasodilation, peripheral edema, and cardiac toxicity. Poisoning can also result in an inhibition of the cholinesterase in nonneuronal tissues, such as the intestine, lung, and blood cells, and this inhibition can be characterized by hyperglycemia, hyperamylasemia, leukocytosis, hemoconcentration, and death. Occupational overexposure to organophosphates may result in delayed neuropathy (the chronic effects of acute exposures). The chronic exposure to the more persistent and more toxic organophosphate pesticides can result in delayed neuropathies, including malignant, inflammatory, and autoimmune disorders, and even death.
