Security differences between Mac OS X and Linux kernels I've used Linux on my desktop for several
years and just about all day to day operations. There's a few things that when I hear they happen on
Mac OS X, I expect the Ubuntu/Debian/whatever solution or something specific to that distribution
of Linux. The first and most-asked difference I've run into is a lack of process handoff. I have a
program that runs in the background as a daemon. I can always go back to it, and it will continue
where it left off. This is because Linux (and any OS X I have ever heard of) will shut down all
background programs when you logout. In other words, there is no way for a program like this to
run in the background on a server and continue when the user logs out. On Linux, you have to have
the ability to have a program running all the time, even if no one is logged in. There might be other
things like this that I have never heard of, and I hope there's documentation on the various
distributions and OS about what they do differently in various scenarios. What I want to know is how
serious a problem this is. For example, I have a Firefox open with some nice custom HTML files, and
the rest of my browser is for non-critical surfing. I normally log out of my account, but when I don't
get away from the computer, I usually do a killall firefox before logoff. If firefox were running as a
daemon for processhandoff, would I have a problem? What other problems are there? How different
is the code behind it in Linux and OS X? A: The process is running when you are logged in to your
account, and it is destroyed when you log out. If you are running a daemon, it will be running all the
time. You only need to be logged in to get your data into the network and keep the daemon running.
A: Process management differs between OS X and other OSes. One of the ways Mac OS X does this
is by not letting you kill a process until it has finished. You may notice this when trying to "
