The operating system typically utilizes a memory management unit (MMU) in conjunction with its page tables to support virtual-to-physical (V-P) address translation. In a typical case, the MMU maintains a table entry structure for translating virtual addresses to physical addresses. The table entry structure may have stored therein a number of virtual address translations.

Typically, each virtual address translation indicates a physical address in which to store a corresponding virtual address translation. A typical system may use a page table to store a number of virtual address translations. The system requires an MMU which maintains a page table and stores a number of virtual address translations therein.

In a typical case, the entire structure of the page table is stored in a main memory of the system. In other words, the entire virtual address translation table is stored in the main memory of the system. When reading (or writing) data from (or to) the main memory, the system typically issues a memory cycle. For a typical system, the memory cycle may involve accessing the entire virtual address translation table in the main memory. As such, the memory cycle is an inefficient use of system resources. Therefore, a need exists for an improved method and apparatus for storing a page table in a cache memory.Z10
