Williams' road to the
2020 US Open began

Thursday in Beijing,
where her bid for a 19th
major championship was
played out against a
backdrop of thousands
of protesters around the

clock and in small but vocal pockets. In a first for a US tennis player, the 23-time major champion had her first official match against a lower-ranked opponent this week at the China Open, where she would face two-time world No. 36 Madison Keys, the Canadian player who,

after years of hard work and dedication, was just a few points away from advancing to a second straight major final.

What followed, as so often when it comes to Williams, was a display of her uncanny ability to handle the chaos. It was a hot and humid day at the National Stadium in

Beijing, the start of three days of matches featuring Williams and a talented group of Americans. Thousands of demonstrators gathered across the street from the stadium, singing and chanting. The state of the art in the development of

ultrasound imaging or medical diagnosis, e.g. with the help of ultrasound imaging, is steadily progressing and, in particular, objectivity and high resolution of the recordings have been achieved in the last years. A higher resolution, which results

in a reduction of the physical size of the ultrasound probe, is desirable for many applications. It is generally known that the resolution of an ultrasound image (scalar image) can be increased by means of multiple reception. At multiple reception ultrasound has

the advantage over other medical imaging modalities, in particular magnetic resonance imaging (MRI) or computed tomography (CT), since the scattering properties of tissue are utilized.

US2007/032938A1 teaches one method for obtaining a high-

resolution image by means of a multi-element transducer and electronic signal processing. With this method, also called SMASH, one so-called 'slice' is obtained from an object in two successive scans and a phase shift between the two scans is recorded.

By means of spatial shift the original scan lines are shifted relatively to one another. By means of delay the scan lines are delayed relative to one another with respect to their original, absolute position. With a subsequent spatial shift and delay the original scan lines are again

shifted relatively to one another and the shifted scan lines are added to one another. The carrier frequency, and, in particular, the frequency shift between the two successive scans, directly affects the resolution of the processed image. In the case of an examination

of a region of interest it is necessary to have an operator-dependent control of the delay between the two successive scans. While with a single-element transducer and electronic signal processing the spatial resolution of the image is determined by the

diameter of the transducer aperture, by use of a transducer array the spatial resolution is determined by the distance between the transducer elements. The smaller the distance between the elements, the higher is the spatial resolution of the image. In the case

of SMASH imaging, the original scan lines are displaced relatively to one another and the original scan lines are added to one another in order to achieve the correct displacement between the individual scan lines. With a single-element transducer and without such an

additional step the line distance of a single-element transducer will be too large to obtain an acceptably high resolution. The result is that the overlap between the scan lines will be too low. The result is that only a small region of an object can be imaged. In an

ultrasound image, an
object is represented as
a set of volume
elements (voxels).
